

```
/** public void run() {  
 * Create the GUI and show it for thread safety; //declared here only to ensure visibility in finally clause  
 * this method should be invoked from the ok  
 * event-dispatching thread //pass each line of input to fInterpreter, and  
 */ //fInterpreter's result  
private static void main(String[] args) {  
    InputStreamReader inputStreamReader = new InputStreamReader(System.in);  
    BufferedReader stdin = new BufferedReader(inputStreamReader);  
    boolean hasRequestedQuit = false;  
    String line = null;  
    List result = new ArrayList();  
    //Create and set up the window //display its data  
    JFrame frame = new JFrame("FocusConceptsDemo");  
    try {  
        frame.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);  
        while (!hasRequestedQuit) {  
            line = stdin.readLine();  
            //note that "result" is passed as an "out" parameter  
            hasRequestedQuit = fInterpreter.parseInput(line, result);  
            display(result);  
            result.clear();  
        }  
    } catch (IOException ex) {  
        System.err.println(ex);  
    }  
    finally {  
        class java.util.GregorianCalendar  
public static void main(String[] args) {  
    //Schedule a job for the event-dispatching thread  
    //creating and showing this application's GUI  
    javax.swing.SwingUtilities.invokeLater(new Runnable()  
    {  
        public void run() {  
            //PRIVATE //GUI();  
            private static final String FBYE = "exit";  
            private Interpreter fInterpreter;  
        }  
        /**  
void printDisplay some text to stdouts {  
    final String[] mvStrings = new String[2];  
    mvStrings[0] = "OK";  
    mvStrings[1] = "Cancel";  
    int choice = JOptionPane.showOptionDialog(null,  
        "Do you want to exit?",  
        "FocusConceptsDemo",  
        JOptionPane.YES_NO_OPTION,  
        JOptionPane.QUESTION_MESSAGE,  
        null, mvStrings, mvStrings[1]);  
    if (choice == JOptionPane.YES_OPTION) {  
        hasRequestedQuit = true;  
    }  
}
```

2. Working with JUnit

Java Test Driven Development with JUnit

**Never in the field of software development
have so many owed so much to so few lines
of code (*referring to JUnit*).**

But a fool with a tool is still a fool.

Martin Fowler

Module Topics

1. JUnit Basic Assumptions
2. The JUnit Application
3. Setting up a JUnit Project in Eclipse
4. Test Methods
5. Assertions
6. Fixture Methods
7. Testing Exceptions

JUnit Basic Assumptions

JUnit Assumptions

- Assumptions about the code to be developed:
 - *Component is designed according to OOP/OOD best practices*
 - *Component functionality is clearly defined during design*
- Assumptions about state of the development:
 - *Architecture of the system is defined: dependencies between components are known*
 - *Acceptance tests exist at the system level so we know how the component should behave within the context of the application*
 - *The levels of acceptable risk and quality are defined*
- Assumed because TDD is part of a larger application development process

The Outside-In Principle

- TDD assumes code development follows the outside-in principle:
 - *Interfaces are designed earlier during the design phase*
 - *Interfaces describe all of the functionality of a component*
 - *Classes are written to implement interfaces*
- Because interfaces are defined during design:
 - *They remain stable and do not change during code development*
 - *Interfaces can change if requirements change*
 - *Interfaces can change if the application architecture changes*
- All interactions take place through a component's interface:
 - *Therefore a component can be fully functionally tested through its interface*

Design by Contract

- Interfaces establish “contracts” between the component and clients that invoke its interface methods
- Each interface method contract has three types of constraints
 - **Preconditions:** *conditions that must be true before a method can be allowed to execute*
 - **Postconditions:** *conditions that must be true after the method executes*
 - **Invariants:** *conditions that must not change as a result of executing the method*
- Tests are easier to implement and code is easier to write when these constraints are known

Command-Query Separation

- CQS is a concept that originated in functional programming
- CQS complements design by contract
- Each method in an interface should one of:
 - **Query:** *Returns information but does not alter the state of the object the message is sent to or cause any side effects*
 - **Command:** *Alters the state of an object or produces a side effect – the only return value is information reporting if the command was successful*
- The principle is often stated as “Asking a question should not change the answer”

TDD Testing Assumptions

- TDD assumptions about how testing should be done:
 - *Test execution should always be automated*
 - *There should be no test code inside the production code*
 - *Testing is not debugging: those tools already exist elsewhere*
 - *There should only be one copy of the production code, there should not be a “test” version of the production code*
 - *The presence of test code should not impact the design of the production code*

The JUnit Application

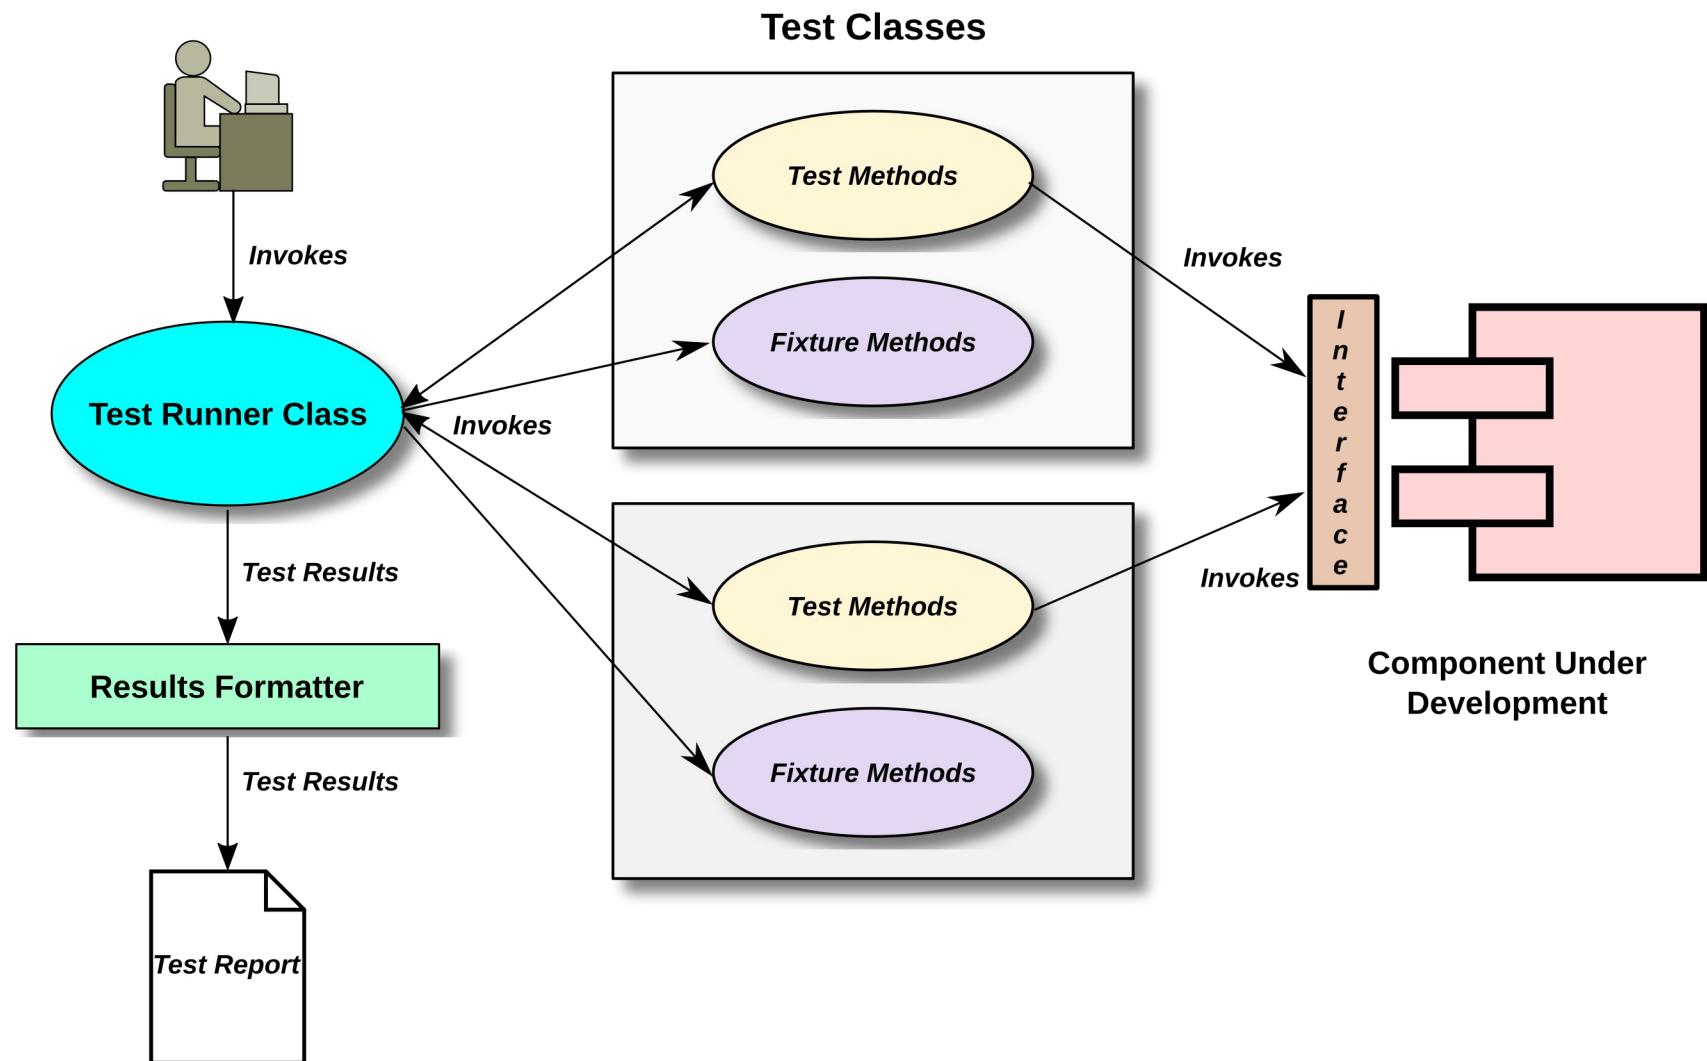

Some JUnit Background

- Kent Beck originally developed SUnit – a testing framework for Smalltalk programmers in the mid 1990s
- Beck and Eric Gamma converted it to a Java framework and called it JUnit on a flight from Zurich to Atlanta in 1997
- The original architecture has come to be known as xUnit and is the basis for many language ports (CppUnit for C++) for example
- The xUnit family of tools shares a characteristic architectural pattern

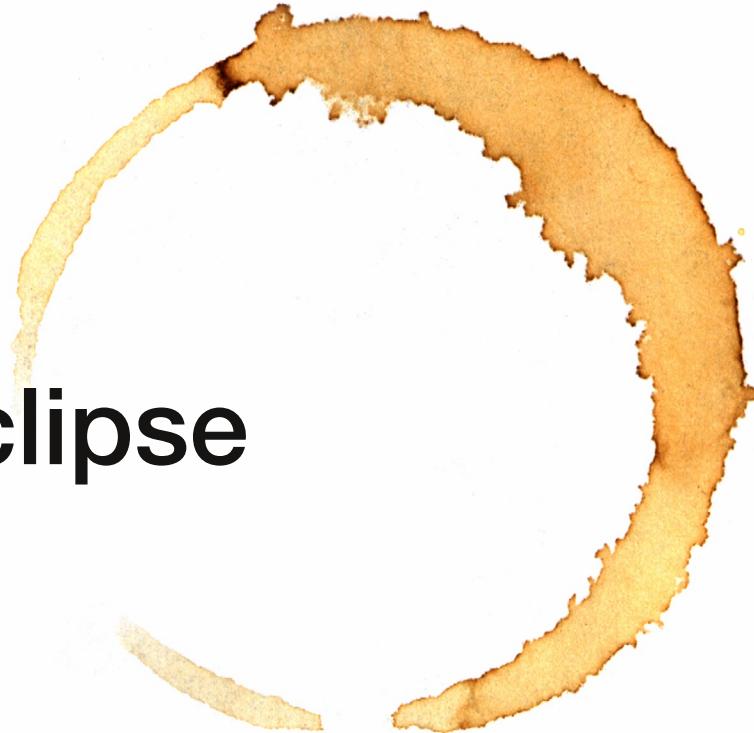

JUnit Architecture

- JUnit is made up of:
 - **Test Runner:** *A class or mechanism that is responsible for executing the tests*
 - **Test Class:** *One or more test classes containing the tests for a component under development*
 - **Test Method:** *Each test is implemented by a test method in a test class*
 - **Test Fixture:** *The state the system has to be in for a test to be run*
 - **Test Suite:** *A set of tests that all share the same test fixture*
 - **Test Execution:** *The running of the test case along with any fixture methods required to set up and tear down the test fixtures*
 - **Test Result Formatter:** *Responsible for reporting on the results of the tests in a usable format*
 - **Assertion Set:** *Functions that verify the results of a test*

JUnit Architecture

JUnit Project in Eclipse

The Calculator Project

- To demonstrate the functionality of JUnit, we will implement a trivial example of a calculator that does basic arithmetic.
- This is not Test Driven Development, this is just experimenting with JUnit
- We will be working within Eclipse
- Initial steps:
 1. *Create the Java project*
 2. *Define the Calculator interface*
 3. *Create the implementing class CalcImp*
 4. *Create the JUnit test class*

```
1
2 public interface Calculator {
3     public int add(int a, int b);
4     public int sub(int a, int b);
5     public int mult(int a, int b);
6     public int div(int a, int b);
7
8 }
```

```
1
2 public class CalcImp implements Calculator {
3
4     public int add(int a, int b) {
5         return 0;
6     }
7
8     public int sub(int a, int b) {
9         return 0;
10    }
11
12    public int mult(int a, int b) {
13        return 0;
14    }
15
16    public int div(int a, int b) {
17        return 0;
18    }
19 }
```

The Project Code

The first image shows the Calculator interface which describes the calculator functionality – which is quite trivial. The second image shows the implementing class where we write the code that implements the functionality described by the interface.

This is an example of “outside-in” development where the interface is defined before we start to write any code. This is the state we want our code in just before we start to do our Test Driven Development.

Also notice that these methods are all queries since they do not change anything inside a calculator object nor do they create any side effects.

Adding the Test Class

- Eclipse is used to add a JUnit test class to the project using a built-in wizard, although we could hand code it
- The test code is in a separate class from the production code
- The test class will be created that creates test method “stubs” that we will use to implement the test methods and fixture methods

```
1+import static org.junit.Assert.*;
8
9 public class CalcImpTest {
10
11
12@Test
13 public void testDiv() {
14     fail("Not yet implemented");
15 }
16
17@BeforeClass
18 public static void setUpBeforeClass() throws Exception {
19 }
20
21@AfterClass
22 public static void tearDownAfterClass() throws Exception {
23 }
24
25@Before
26 public void setUp() throws Exception {
27 }
28
29@After
30 public void tearDown() throws Exception {
31 }
32 }
33 }
```

The Generated Stubs

This is what the final result of the using the wizard looks like, although the fixture methods have been moved to end of the file for readability.

The Test Method

- The JUnit runner uses the annotations to find the test methods
 - *All methods with the @Test annotation are test methods*
 - *The auto-generated names on the methods should be changed to something that more meaningful*
 - *However test methods must return void and take no arguments*
- The other methods with other annotations (@Before, @After, etc) are fixture method stubs
- At this point we can run the test method using the built in Eclipse JUnit runner

The screenshot shows the Eclipse IDE interface. On the left, the 'JUnit' perspective is active, displaying the 'Package Explorer' and 'JUnit' view. The 'JUnit' view shows a summary: 'Finished after 0.018 seconds', 'Runs: 1/1', 'Errors: 0', and 'Failures: 1'. Below this, it lists 'CalcImpTest [Runner: JUnit 4] (0.001 s)' and 'divTest001 (0.001 s)', where 'divTest001' is highlighted in blue. On the right, the 'CalcImp.java' and 'CalcImpTest.java' tabs are open. The code in 'CalcImpTest.java' is as follows:

```
1+import static org.junit.Assert.*;
8
9 public class CalcImpTest {
10
11
12 @Test
13 public void divTest001() {
14     fail("Not yet implemented");
15 }
16
17 @BeforeClass
18 public static void setUpBeforeClass() {
19 }
20
21 @AfterClass
22 public static void tearDownAfterClass(
23 )
24
25 @Before
26
```

Running the Tests

By selecting the “Run as JUnit test” option, Eclipse calls the JUnit default runner class which then looks through the test class and runs all of the @Test methods.

The Eclipse built in results formatter reports that 1 test was run and 1 test failed. The test failed because when the stub was generated, a fail assertion was placed in the body as a reminder to add the code to test method. The fail() assertion ensures the test fails every time it is run.

The test methods are not guaranteed to run in any particular order.

The Test Results

- JUnit cannot understand what a test “means” so it relies on us to tell it whether or not a test has passed or failed
- If an assertion exception is thrown then JUnit marks the test as failed
 - *The fail() method is an assertion that throws an exception every time it executes*
- Tests that don’t throw assertion exceptions are considered to have passed
- Best practice: always have a fail() method in a test method until the test code is written

The screenshot shows the Eclipse IDE interface. On the left, the 'Package Explorer' view is visible. In the center, the 'JUnit' view displays the test results: 'Finished after 0.014 seconds', 'Runs: 1/1 (1 skipped)', 'Errors: 0', and 'Failures: 0'. A green progress bar indicates the test was skipped. On the right, the 'CalcImpTest.java' file is open, showing the following Java code:

```
1+import static org.junit.Assert.*;
9
10 public class CalcImpTest {
11     @Ignore
12     @Test
13     public void divTest001() {
14         fail("Not yet implemented");
15     }
16
17     @BeforeClass
18     public static void setUpBeforeClass() {
19     }
20
21     @AfterClass
22     public static void tearDownAfterClass(
23     )
24
25     @Before
26 }
```

Ignoring Tests

The `@Ignore` annotation has been added to the test methods. This causes JUnit to skip the test and not count it as a pass or failure. The `@Ignore` annotation is used to suppress reporting about a test until we actually want to run it. Ignoring a test method is a lot safer than editing out the `fail()` annotation.

Because no test has failed, JUnit reports that all of the tests passed but one test was skipped.

The screenshot shows the Eclipse IDE interface. On the left, the 'Package Explorer' view is visible. In the center, the 'JUnit' view displays the results of a test run: 'Finished after 0.014 seconds', 'Runs: 1/1', 'Errors: 0', and 'Failures: 0'. Below this, a green progress bar indicates a successful run. On the right, the 'CalcImpTest.java' file is open, showing Java code for a JUnit test class. The code includes imports for org.junit.After and org.junit.Test, and annotations for @BeforeClass, @AfterClass, and @Before.

```
1+import org.junit.After;
2
3public class CalcImpTest {
4
5    @Test
6    public void divTest001() {
7        //fail("Not yet implemented");
8    }
9
10   @BeforeClass
11   public static void setUpBeforeClass() {
12   }
13
14   @AfterClass
15   public static void tearDownAfterClass() {
16   }
17
18   @Before
19   public void setup() throws Exception {
20
21
22
23 }
```

Passing Tests

In the example, the `@Ignore` annotation has been removed and the `fail()` assertion commented out. Now the test passes vacuously since it doesn't do anything that informs JUnit a failure has taken place. Notice the only difference between this output and the previous slide is that in this case no tests are reported as being skipped.

The screenshot shows the Eclipse IDE interface. On the left, the 'JUnit' view displays the results of a test run: 'Finished after 0.017 seconds', 'Runs: 1/1', 'Errors: 1', and 'Failures: 0'. A blue bar indicates the error. Below this, the 'CalcImplTest [Runner: JUnit 4] (0.001 s)' section is expanded, showing the test method 'divTest001 (0.001 s)'. On the right, the 'CalcImplTest.java' editor shows the Java code for the test class:

```
1+import org.junit.After;
2
3public class CalcImplTest {
4
5    @Test
6    public void divTest001() {
7        int x = 1/0;
8    }
9
10   @BeforeClass
11   public static void setUpBeforeClass() {
12   }
13
14   @AfterClass
15   public static void tearDownAfterClass() {
16   }
17
18   @Before
19   public void setup() throws Exception {
20
21
22
23 }
```

Errors are NOT Failures

In the example above, a Java error (divide by zero) has been added to the code. This caused an exception to be thrown that was not generated by an assertion statement. Because the divide by zero exception is not an assertion exception, this test has not failed or passed from a testing point of view because it could not be run.

Notice that this is reported in the results window as an error and not as a failure.

Test Methods

Writing Test Methods

- Each test method is a single test case consisting of
 - *A test input*
 - *A description of the system state required for test execution*
 - *The expected correct output*
- The test method:
 - *Acquires an instance of the component under development*
 - *Invokes the method being tested using the test input*
 - *Compares the actual value returned with the expected value*
 - *If they two values match then the test passes, otherwise it fails*
- Putting the system into the required test state is done with the fixture methods

```
1+import static org.junit.Assert.*;
8
9 public class CalcImpTest {
10
11@Test
12 public void divTest001() {
13     Calculator c= new CalcImp();
14     int retVal = c.div(6,3);
15     if (retVal != 2) {
16         fail("divTest001 failed");
17     }
18 }
19
20@BeforeClass
21 public static void setUpBeforeClass() {
22 }
23
```

Implementing a Test Case

Consider test case divTest001() for the Calculator div() method. The test case specifies inputs of 6 and 3 and an expected value of 2. An instance “c” of the calculator object is created and the result of invoking c.div(6,3) is stored in retVal

If retVal is not 2, a fail() exception is thrown and the test fails

In the next section, we will improve the code with more natural Assertions.

The screenshot shows the Eclipse IDE interface. On the left, the 'JUnit' view displays the results of a test run: 'Finished after 0.018 seconds', 'Runs: 1/1', 'Errors: 0', and 'Failures: 1'. A single failure is listed under 'CalcImpTest [Runner: JUnit 4] (0.002 s)': 'divTest001 (0.002 s)'. On the right, the code editor shows the Java source code for 'CalcImp.java'. The code defines a class 'CalcImp' that implements the 'Calculator' interface. It contains four methods: add, sub, mult, and div, each returning 0.

```
1 public class CalcImp implements Calculator
2
3     public int add(int a, int b) {
4         return 0;
5     }
6
7     public int sub(int a, int b) {
8         return 0;
9     }
10
11    public int mult(int a, int b) {
12        return 0;
13    }
14
15    public int div(int a, int b) {
16        return 0;
17    }
18
19
```

Test Case Failure

Running the tests now reports a failure because we haven't yet implemented the production code that makes the test pass.

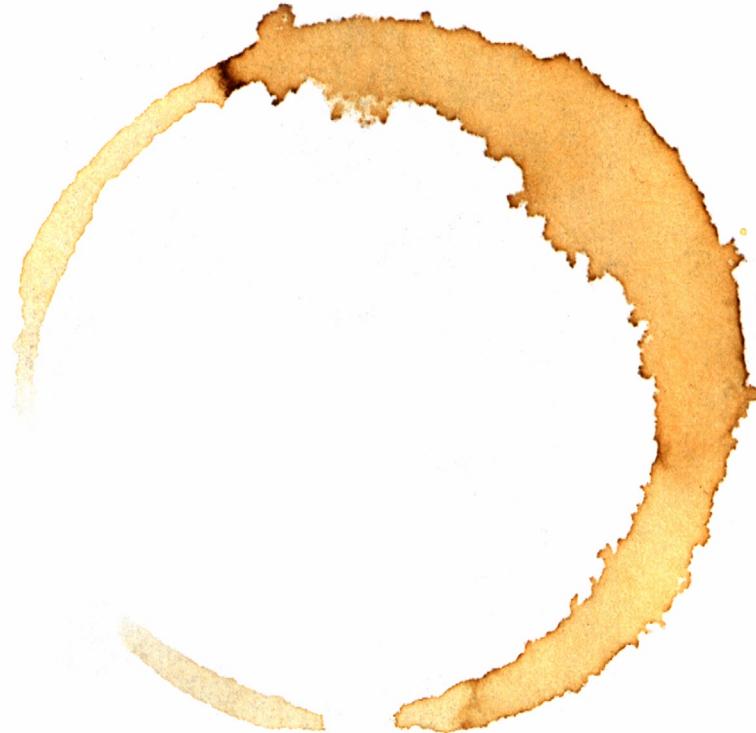

The screenshot shows the Eclipse IDE interface. On the left, the 'JUnit' view displays the results of a test run: 'Finished after 0.015 seconds', 'Runs: 1/1', 'Errors: 0', and 'Failures: 0'. A green progress bar indicates a successful run. On the right, the code editor shows the 'CalcImp.java' file, which implements the 'Calculator' interface. The code contains four methods: add, sub, mult, and div, all returning 0. The 'CalcImpTest.java' tab is also visible at the top of the editor.

```
1 public class CalcImp implements Calculator
2
3     public int add(int a, int b) {
4         return 0;
5     }
6
7     public int sub(int a, int b) {
8         return 0;
9     }
10
11    public int mult(int a, int b) {
12        return 0;
13    }
14
15    public int div(int a, int b) {
16        return a/b;
17    }
18
19
```

Passing the Test

The production code has been added to the div() method and the test now passes.

Assertions

JUnit Assertions

- Assertions are statements that evaluate to true or false
- If an assertion is false then an exception is thrown, otherwise no action is taken
- Assertions express test conditions in a readable form, for example:
 - `assertEquals([msg],expected, actual)` compares two values, if they are not equal, the assertion fails (“msg” is an optional message to be printed if the assertion fails)
 - `assertEquals(expected, actual, delta)` is a form used for floating point numbers where two values are “equal” if $|expected-actual|<\delta$
 - `assertTrue(val)` where val is a boolean predicate that should evaluate to “true”
- A full list of assertions is provided in the student manual

The screenshot shows the Eclipse IDE interface. On the left, the 'JUnit' view displays a green progress bar indicating a successful run: 'Runs: 1/1 Errors: 0 Failures: 0'. Above this, the status bar says 'Finished after 0.016 seconds'. On the right, the code editor shows the Java source code for 'CalcImpTest.java'. The code includes imports for JUnit assertions, a class definition with a test method 'divTest001' using assertEquals, and annotations for @BeforeClass and @AfterClass.

```
1+import static org.junit.Assert.*; 8
9 public class CalcImpTest {
10
11@ 11@Test
12 public void divTest001() {
13     Calculator c= new CalcImp();
14     assertEquals("Oops!",2,c.div(6,3));
15     // or any of the following
16     assertTrue("Oops", 2 == c.div(6,3));
17     assertFalse("Oops", 2 != c.div(6,3));
18 }
19
20@ 20@BeforeClass
21 public static void setUpBeforeClass() throws
22 {
23 }
24@ 24@AfterClass
25 }
```

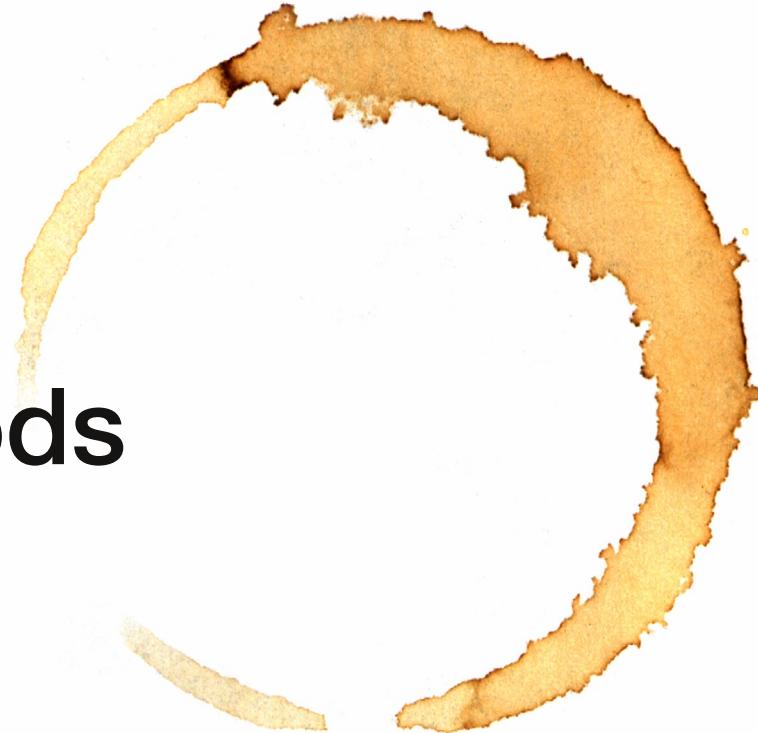

Readable Forms of Assertions

The use of the different forms of assertions allows us to state the test conditions in a much more natural and readable manner. JUnit does not care what form of the assertion is used which means that we choose the one that reads most naturally.

For example, there are three forms used in the test method and JUnit will accept any one of them, but the first assertion used would be preferable because it communicates more clearly what the method is testing to those reading or maintaining the code.

The use of the different forms allows us to write more streamlined and compact code as well.

Fixture Methods

Testing Exceptions

- Fixture Methods are run to set up and tear down tests
 - *Set up methods prepare the test environment and system state*
 - *Tear down methods undo what set up methods do*
- Fixture methods are identified by annotations
 - *Methods with @BeforeClass are executed once before any tests are run*
 - *Methods with @AfterClass are executed once after all tests have run*
 - *Methods with @Before are all executed before each test is run*
 - *Methods with @After are all executed after each test is run*
- Fixture methods with the same annotation are not guaranteed to run in the order they appear in the code

```
Calculator.java CalcImp.java CalcImpTest.java
```

```
11@Test
12 public void divTest001() {
13     Calculator c= new CalcImp();
14     System.out.println("      Div001");
15     assertEquals("Oops!",2,c.div(6,3));
16 }
17@Test
18 public void divTest002() {
19     Calculator c= new CalcImp();
20     assertEquals("Oops!",-2,c.div(-6,3));
21     System.out.println("      Div002");
22 }
23
24@BeforeClass
25 public static void setUpBeforeClass() throws Exception {
26     System.out.println("*** BeforeClass ");
27 }
28
29@AfterClass
30 public static void tearDownAfterClass() throws Exception {
31     System.out.println("*** AfterClass ");
32 }
33
34@Before
35 public void setUp() throws Exception {
36     System.out.println(" --- Before ");
37 }
38
39@After
40 public void tearDown() throws Exception {
41     System.out.println(" --- After ");
42 }
43 }
```

Fixture Methods

In the code, we have added some dummy fixture methods and a second test method.

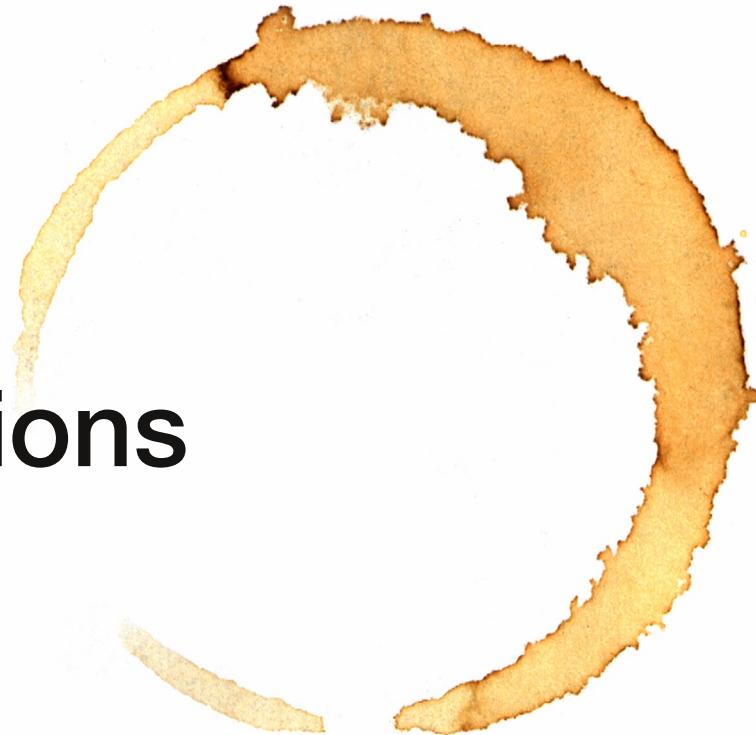

The screenshot shows the Eclipse IDE interface with the 'Console' tab selected. The output window displays the following text:

```
<terminated> CalcImplTest [JUnit] /usr/lib/jvm/java-1.8.0-openjdk-1.8.0.121-8.b14.fc24.x86  
*** BeforeClass  
    --- Before  
        Div001  
    --- After  
    --- Before  
        Div002  
    --- After  
*** AfterClass
```

Fixture Method Output

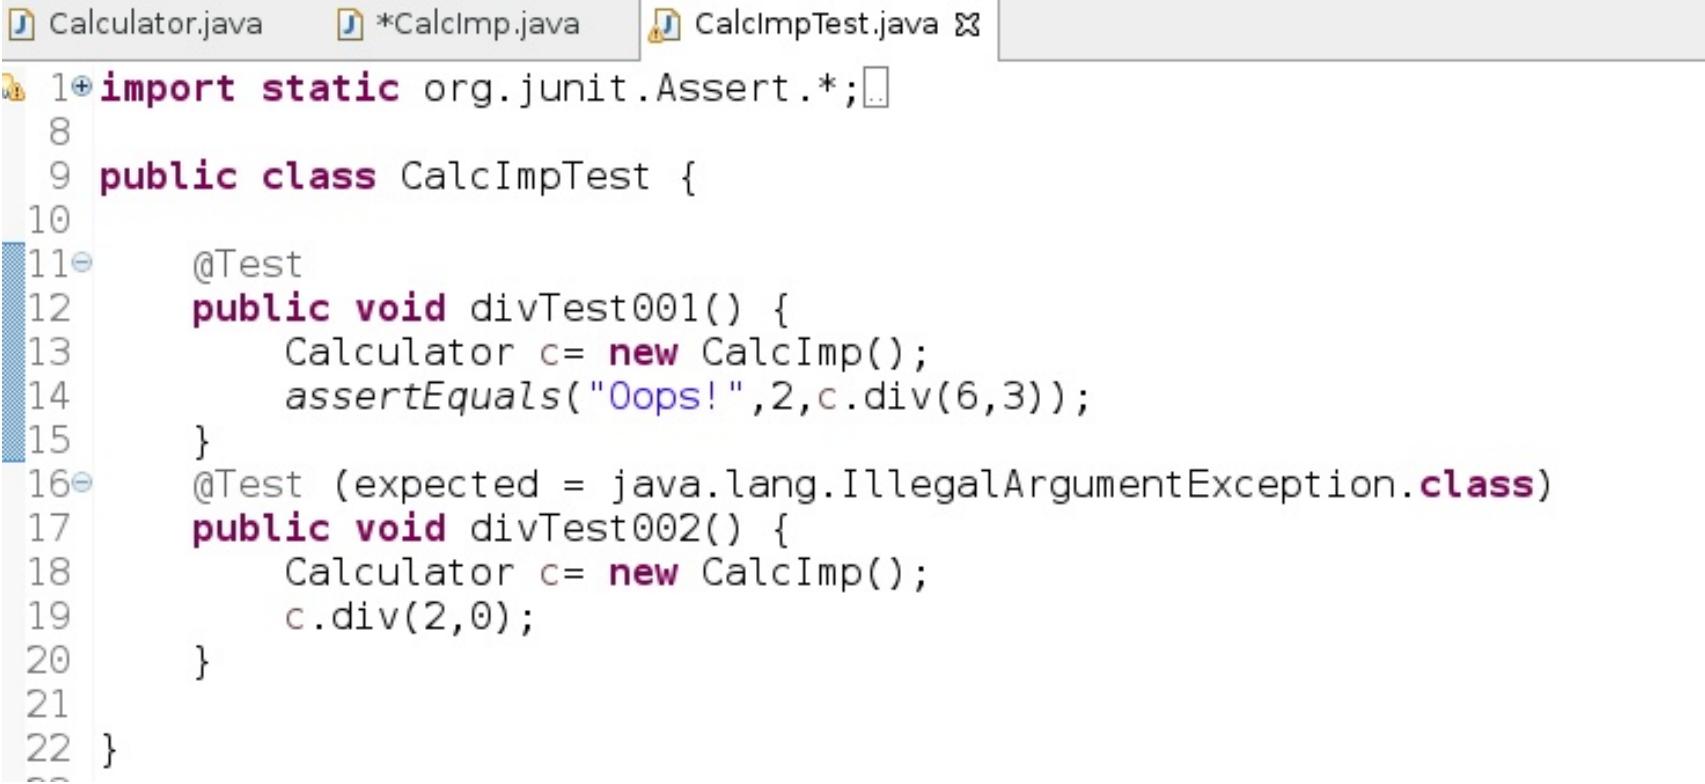

Running the test and looking at the console output, the sequence of execution of the fixtures and the test methods is clearly seen.

Testing Exceptions

Testing for Exceptions

- Sometimes a test expects an exception to be thrown in order to pass
 - *The standard assertions do not allow us to check this case*
 - *Instead we identify the exception to be thrown in the annotation*
- The assertion syntax is:
 - `@Test(expected = <java exception class>)`
- The test will pass only if the specified exception is thrown
- The test will fail if no exception is thrown
- The test will fail if any exception other than the specified one is thrown

The screenshot shows a Java code editor with three tabs at the top: 'Calculator.java', '*CalcImp.java', and 'CalcImpTest.java'. The 'CalcImpTest.java' tab is active, displaying the following code:

```
1+import static org.junit.Assert.*;
8
9 public class CalcImpTest {
10
11@    @Test
12    public void divTest001() {
13        Calculator c= new CalcImp();
14        assertEquals("Oops!",2,c.div(6,3));
15    }
16@    @Test (expected = java.lang.IllegalArgumentException.class)
17    public void divTest002() {
18        Calculator c= new CalcImp();
19        c.div(2,0);
20    }
21
22}
```

The Exception Test Method

In the second test method, we are checking to see if the production code throws an `IllegalArgumentException` when the `divide` method divides by zero.

The screenshot shows the Eclipse IDE interface. The top bar has tabs for 'Package Explorer' (selected), 'JUnit' (with a red error icon), and other project files. Below the tabs is a toolbar with icons for file operations like New, Open, Save, and Delete, along with others for search and navigation.

The main workspace is divided into two panes. The left pane displays the JUnit test results:

- Text: "Finished after 0.018 seconds"
- Statistics: "Runs: 2/2", "Errors: 1", "Failures: 0".
- Test tree:
 - CalclmpTest [Runner: JUnit 4] (0.003 s)
 - divTest001 (0.000 s)
 - divTest002 (0.003 s)** (highlighted in blue)

The right pane shows the source code for `Calclmp.java`:

```
1 public class Calclmp implements Calculator {  
2     public int div(int a, int b) {  
3         return a/b;  
4     }  
5     public int add(int a, int b) {  
6         return 0;  
7     }  
8     public int sub(int a, int b) {  
9         return 0;  
10    }  
11    public int mult(int a, int b) {  
12        return 0;  
13    }  
14}
```

Running the Exception Test

Since the code to check for a division by zero does not yet exist, the test fails. Notice that this is one time when an error and failure are the same thing. The error occurred because Java threw an `ArithmeticException` however the test failed because it was expecting an exception but the wrong type of exception was thrown.

The screenshot shows the Eclipse IDE interface. On the left, the 'JUnit' perspective is active, displaying the 'Package Explorer' and 'JUnit' view. The 'JUnit' view shows a green progress bar indicating successful execution of 2/2 tests. Below the progress bar, it says 'Finished after 0.015 seconds' and lists 'Errors: 0' and 'Failures: 0'. A blue bar highlights the 'CalcImpTest [Runner: JUnit 4] (0.000 s)' entry. On the right, the 'Calculator.java' editor is open, showing the following Java code:

```
1 public class CalcImp implements Calculator {  
2     public int div(int a, int b) {  
3         if (b == 0)  
4             throw new IllegalArgumentException();  
5         return a/b;  
6     }  
7     public int add(int a, int b) {  
8         return 0;  
9     }  
10    public int sub(int a, int b) {  
11        return 0;  
12    }  
13}  
14  
15  
16  
17
```

Running the Exception Test

Once the production code is added to perform the check for zero and throw the correct exception, the tests pass.

End of Module 2
